ABSTRACT

A hub dynamo is compacted into a small diameter size while ensuring the generation of a high voltage of electric power. A coil ehamber CR-chamber, formed between a pair of main iron eores 10-cores, is partitioned in the axial direction by three at least one sub iron eores 11-core to form a first, second, third and fourth plurality of coil ehambers (CR 1, 2, 3 and 4); on these chambers. On the coil chambers (CR 1, 2, 3 and 4), one a coil wire 13 wire is wound in order in a state such that the winding direction changes alternately; and magnetic alternately between adjacent coil chambers. Magnetic flux collectors 15 collectors are connected with to the outer circumference of the main/sub iron cores 10 and 11 cores and include a plurality of first magnetic flux collector 15 collectors connected with the first, third and fifth odd numbered iron cores (10-1), (11-3) and (10-5) and a (counting from either end) and a plurality of second pole piece 15 magnetic flux collectors connected with the second and fourth even numbered iron cores (11-2), (11-4), which are disposed alternately cores.
